A shared vision:

‘clean, healthy, safe, productive and biologically diverse oceans and seas’
Charting Progress 2 and the Feeder Reports

Based on the monitoring, research, assessment, musing, cogitations, considerations and ruminations of many, many, many, many scientists across the UK.
CP2 Regions

• Eight (8) regions based on bio-geographical features rather than administrative boundaries.

• Summaries based on the 8 CP2 Regions where appropriate.

**Hazardous substances**
Main sources are inputs from rivers, the atmosphere, various industries and agriculture. These sources are subject to controls. In some limited areas marine biota are at risk, particularly near to the main sources in industrialised estuaries. Reservoirs in sediments due to historical contamination will take many years to dissipate to background concentrations due to persistency of the substances.

**Radioactivity**
Main sources are discharges from the nuclear sector and hospitals and the offshore oil and gas industry which discharges naturally occurring radionuclides. Received doses of radioactivity to both humans and wildlife continue to be well within regulatory limits.

**Eutrophication**
Main sources are inputs of nitrogen (N) and phosphorus (P) from sewage works and agriculture. Ecosystems are at risk if eutrophication occurs. A few very small coastal harbours and embayments with limited water circulation experience eutrophication problems. Nitrogen and phosphorus inputs to these are controlled.

**Oil/chemical spills**
Main sources are accidental spills from ships and the offshore oil and gas industry. Ecosystems, habitats and species may be at risk if loads are significant. Where significant tonnages are split, regional monitoring programmes are implemented to assess risk. Assessment of cumulative impact is problematic.

**Beach litter**
Main sources are the general public, fishing, sewage discharges and shipping. Aesthetic, economic and environmental impacts may occur if levels are high. Only limited data available for Regions 6, 7 and 8.

**Offshore litter**
Main sources are from fishing/shipping and plastics discarded on land and at sea. There is insufficient evidence or criteria to assess impacts and state on a regional basis, but several surveys indicate that marine litter accumulates in certain locations due to sea currents.

**Noise**
Main anthropogenic sources are explosions used in construction and demolition, shipping, seismic surveys, offshore construction and industrial activities and sonar of various types. There is insufficient evidence or criteria to assess impacts and state on a regional basis, but research indicates that cetaceans and fish may be affected by specific noises.

Intertidal rocky and nearshore subtidal rocky habitats are in reasonable condition while many seabed sedimentary habitats have been adversely affected, particularly by mobile fishing gears.

The diversity and overall abundance of soft-bottom demersal fish have improved appreciably in most regions over the past 5 years; this is probably due to reductions in fishing effort.

Commercial fisheries continues to exert a significant pressure on target and non-target fish populations; overall, fish stocks are still depleted compared to 50 to 100 years ago.

Populations of waterbirds have improved in most regions.

Harbour seal populations have declined in Scottish and North Sea regions.

Climate change is having an impact on fish populations, may be a factor in the population decline observed for seabirds in many regions and is impacting the species composition of intertidal rocky communities.

Cetacean populations are considered to be in good condition across the North Sea.

Based on the assessment in Chapter 5 (Productive Seas), fishing mortality has declined significantly in many of the assessed fish stocks in UK waters and although there is some way to go before the majority of commercial stocks are considered to be exploited at safe levels, there have been marked improvements. The main pressure is removal of fish through commercial fishing activities. However, for some stocks the change in water temperature is thought to be a contributing factor.

<table>
<thead>
<tr>
<th>Estuarine fish</th>
<th>NP</th>
</tr>
</thead>
</table>
| The lack of data available for estuarine fish makes any conclusions tentative. What evidence there is suggests an overall increase in diversity and number of fish linked to cleaner estuaries but with a significant reduction in eel recruitment reflecting an Atlantic-wide trend. Although estuarine communities have improved in some Regions, the recent decline in eels (and salmon) often reduces the overall score.

<table>
<thead>
<tr>
<th>Harbour seals</th>
<th>NP</th>
</tr>
</thead>
</table>
| Harbour seals have been decreasing in abundance, dramatically in some areas (up to 50%), particularly in Regions 1, 2 & 7. Although subjected to various pressures (competition with grey seals, predation by killer whales, unregulated shooting, and declines in important prey species such as sand eels) the reason for this decline is still unknown.

<table>
<thead>
<tr>
<th>Grey seals</th>
<th>NP</th>
</tr>
</thead>
</table>
| Although grey seals are generally not experiencing any problems, populations in Regions 4, 5 & 6 are no longer increasing. The reasons for this apparent plateau in the population are not clear at present.

<table>
<thead>
<tr>
<th>Cetaceans</th>
<th>NP</th>
</tr>
</thead>
</table>
| Historic by-catch is suspected to be responsible for low numbers of cetaceans in the Eastern Channel (Region 3) but more data are required to confirm the cause. Impact of persistent contaminants is decreasing.

<table>
<thead>
<tr>
<th>Seabirds</th>
<th>NP</th>
</tr>
</thead>
</table>
| There have been substantial declines in seabird abundance in north and north-west Scotland where the main pressures are climate change and the introduction of non-indigenous species (e.g. rat and mink affecting nesting sites). Tern numbers breeding in the Eastern Channel have declined due to natural causes (i.e. predation and storm events).

<table>
<thead>
<tr>
<th>Waterbirds</th>
<th>NP</th>
</tr>
</thead>
</table>
| Waterbirds are generally not experiencing any problems and their status has been improving since the mid-1970s. An exception is Region 5 where waterbird populations are moving east, away from traditional sites; the reasons for this change are unknown but may be due to climate change.

Although subjected to various pressures (competition with grey seals, predation by killer whales, unregulated shooting, and declines in important prey species such as sand eels) the reason for this decline is still unknown.
Few or no problems relating to radioactivity, eutrophication, microbiological contaminants or algal toxins in seafood.

Hazardous substances reduced in most regions. Impacts are localised in industrial estuaries and coastal areas. Some persistent chemicals can still be detected in marine sediments and species in these areas.

Litter found on all surveyed beaches. More limited evidence shows it is also present in the sea and on the sea floor.

Unable to make an assessment of the impact of noise.

**Clean and Safe Seas**
Oil and gas contribute the most to the economy. Renewable energy and flood and coastal defence activities have more than doubled since 2005.

Fishing mortality has declined. There are indications of improvements in sustainability for some fish stocks. Many assessed stocks are fished at rates above the levels expected to provide the highest long-term yield.

Socio-economic activities put varying degrees of pressure on the marine environment: damage and loss of seabed habitat from fishing; pollution from land and marine-based sources; introduction of invasive species from shipping.

We are not yet able to accurately assess the impact of all pressures on our seas (e.g. underwater noise), nor able to assess the cumulative effects of pressures and to determine whether use is sustainable.

Our seas are economically productive. Most activities are highly regulated to limit impacts and, aside from fisheries, have localised pressure footprints.

Productive Seas
Climate change caused by human activity is likely to play an increasingly significant role in the changing state of our seas

- Warmer sea temperatures since the 1980s have increased the growing season.

- Distributions of different types of plankton are likely to shift in response to warming climate; this may not be smooth.

- The distributions of some North Sea fish have responded to increasing sea temperatures by moving northward and to deeper waters.

- Increased sea water acidity is likely to affect species and habitats, such as cold-water coral reefs and shellfish.
Common issues and regional perspectives

- All regions support, or are affected by, human activities.
- The varied extent of human uses leads to different pressures.
- Fishing continues to be a widespread pressure.
- Threat due to pollution by hazardous substances is greatest around the coasts of England and Wales.
- There are significant changes in the populations of seabirds and seals across different regions.
Challenges

- Quality of the evidence base
- Harmonized assessment criteria
- Consistent baselines
- Appropriate scales
- Integrated assessment
- Need for better tools and wider coverage
- Communicating key findings simply and effectively
